

Chapter–8

Future Scope of Research

Organic farming goes both by concept and application. By default Indian agriculture has been continued as organic farming until 1960s, when this rich tradition had been intervened with chemicalised agriculture in the form fertilizer, pesticides and so on. The permissive effect of chemical agriculture on both biodiversity and human health have been accepted by the scientist all over the world and organic farming has been accepted thereafter, as one of the important options to make both ecology and economy healthy and interwoven.

The empirical studies as documented in this dissertation have left behind the score future research agenda. This are –

- The registration of organic farming and people awareness in this regard offer a very needful area of research.
- The impact of organic farming on the surrounding ecology and its dividends on farm economy need to undergo a meticulous research, so that an operational model can be developed there with.
- The supply chain and the market segments of the products from organic farming need to be scrutinized and constraints thereafter, need to be identified through the befitting market research.
- The gender studies in organic farming itself offer a niche area of research where in lot of relevance variables are to be elucidated.
